# Outline

**Motivation**

**Some WIMP direct detection physics**

**Introducing the experiment**

**Detection principle**

**Analysis chain**

**Physics potential of CDMS**

**Conclusions**

Structure forming needs initial, gravitational seeds.

Strong evidences for Dark Matter from astronomy.

The nature of the dominating part of matter in the universe is unknown.

Extensions of the SM give good candidates for WIMPs.

Maybe something completely different.

# Recoil spectra of WIMP-nucleus scattering

$$\frac{dR_{(v_E, v_{esc})}}{dE_R} = \frac{R_0}{E_0 \cdot r} \cdot f(v_0, v_E, v_{esc}, E_0, r) \cdot F^2(q \cdot r_n)$$

$$R_0 = \frac{2}{\sqrt{\pi}} \cdot \frac{N_0}{A} \cdot \frac{\rho_{WIMP}}{m_{WIMP}} \cdot \sigma_0 \cdot v_0$$

$$E_0 = \frac{1}{2} \cdot m_{WIMP} \cdot v_0^2$$

$$r = \frac{4 \cdot M_T \cdot m_{WIMP}}{(m_{WIMP} + M_T)^2}$$

$v_0$  : mean velocity of WIMPs  
~ 220 km/s

$v_{esc}$  : escape velocity of WIMPs  
~ 544 km/s

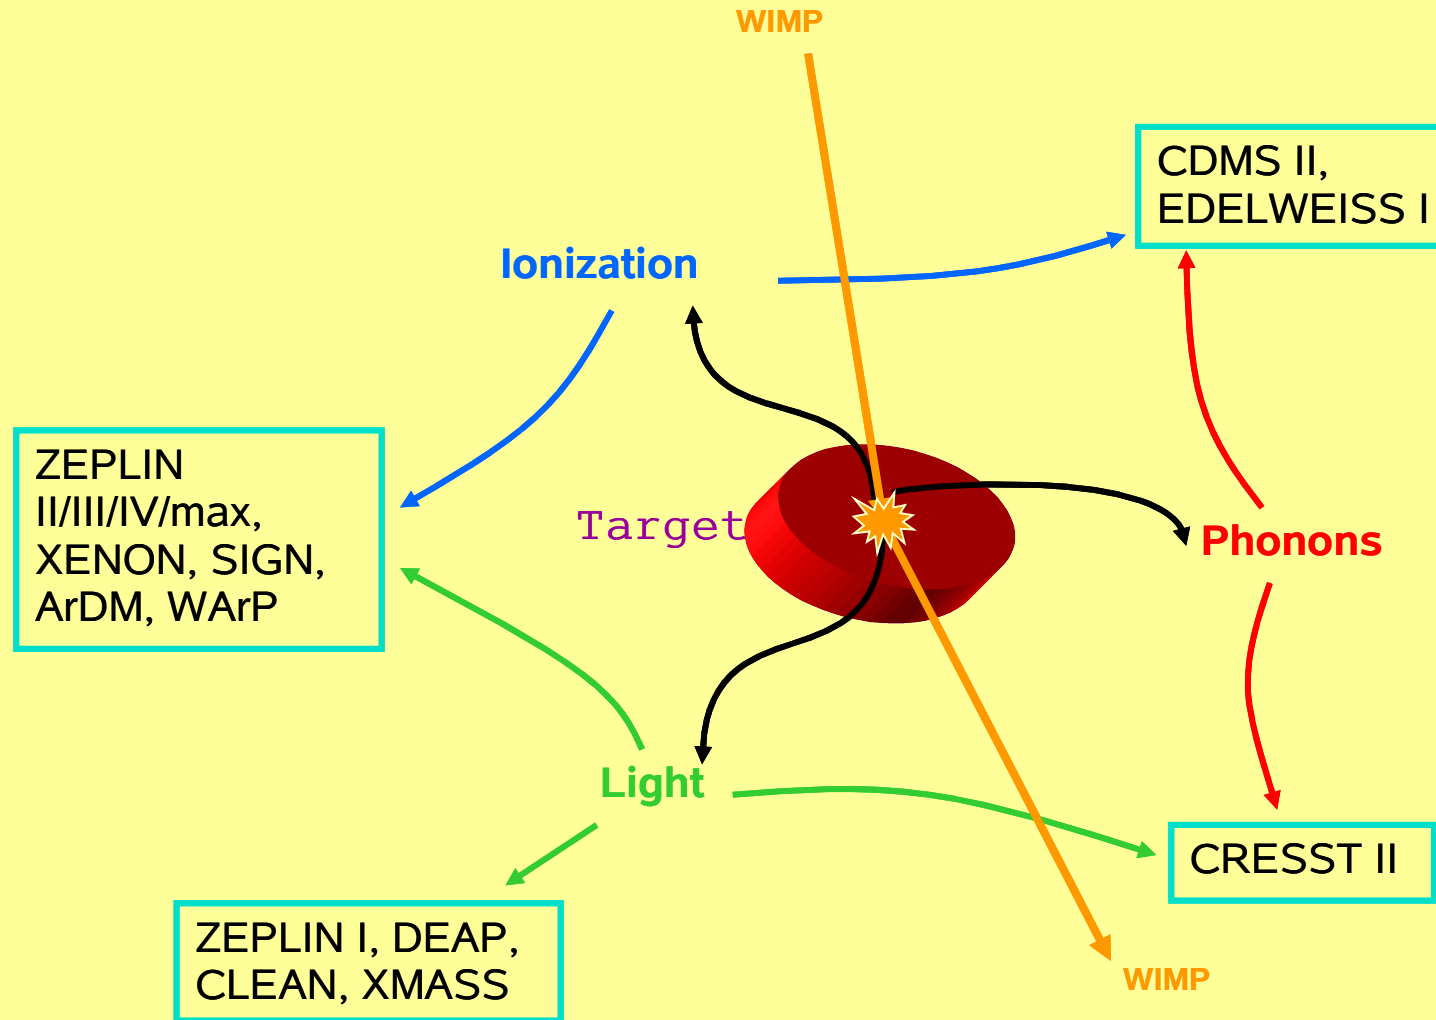

$v_E$  : earth velocity ~ 232 km/s

$\rho_{WIMP}$  : local WIMP density  
~ 0.3 GeV/cm<sup>3</sup>

$\sigma_0$  : WIMP-nucleus crosssection,  
scales with  $A^2$  (SI)

# Detection and background rejection techniques

Several channels can be used to discriminate background from signal for low energetic recoils ( $\sim < 100$  keV).

Apart from background discrimination, the minimization of all possible background sources (natural radioactivity, cosmic rays ...) is necessary.

# Going underground

# CDMS detectors

CDMS uses semiconductor (Ge; Si) detectors which measure the ionization and phonon signal of a recoil. These two signals provide an event by event discrimination between background (mainly gammas) and nuclear recoils (expected WIMP signal).

CDMS detectors are operated at cryogenic temperatures ( $\sim 20$  mK).

CDMS II now runs 5 towers (each containing 6 1 cm thick detectors).

 = Ge (250g)  
 = Si (100g)

# Shielding of the detectors

Excellent shielding necessary to suppress external neutron and gamma background.

# Ionization Signal

A drift field of -3V/cm (-4V/cm) is applied to the Ge (Si) detectors.

Electron – Hole pairs created by an interaction drift towards the electrodes, inducing charge on the inner ( $Q_{\text{inner}}$ ) and outer ( $Q_{\text{outer}}$ ) electrode.

Since interactions at the crystal edges can have an incomplete charge collection, the outer electrode acts as a guard ring.

Events with a significant signal on  $Q_{\text{outer}}$  are rejected in the analysis.

$Q_{\text{outer}}$  constrains our fiducial volume.

Capacitive readout of the signal.

# Calorimetry using phonons

Phonons break Cooper-Pairs in super conducting Al film.

Quasiparticles ( $e^-$ ) diffuse to the W TES, and deposit their energy → Temperature rises.

Rising temperature → higher resistance → lower current;

For stable operation apply constant Voltage.

$$I = \frac{U_{const}}{R} \quad P = \frac{U_{const}^2}{R}$$

Signal is a dropdown in current, which is readout by a SQUID.

# Getting more discrimination power for low yield events by segmented phonon readout

Each quadrant consists of 37 cells with 28 TESs per cell.

Segmented phonon readout useful for localization of an event in x-y plane.

Event location in the x-y plane can be reconstructed in two ways:

- Partition of energy among the four quadrants.
- Relative delay of phonon pulses in four quadrants.

Differences in the timing parameters in several quadrants can be used to discriminate surface events.

# Energy calibration for low energetic events

We are using the 10.4 keV line of the neutron activated Ge isotope:

to determine the energy resolution of the charge and phonon channel for low energetic recoils.

In both channels we achieve an energy resolution of:  $\sim 3 \%$

# Signal and background interactions

Suppressed ionization signal for nuclear recoils.

True recoil energy of an event:

$$E_{phonon}$$

Yield defined as:

$$y = \frac{E_{charge}}{E_{phonon}}$$

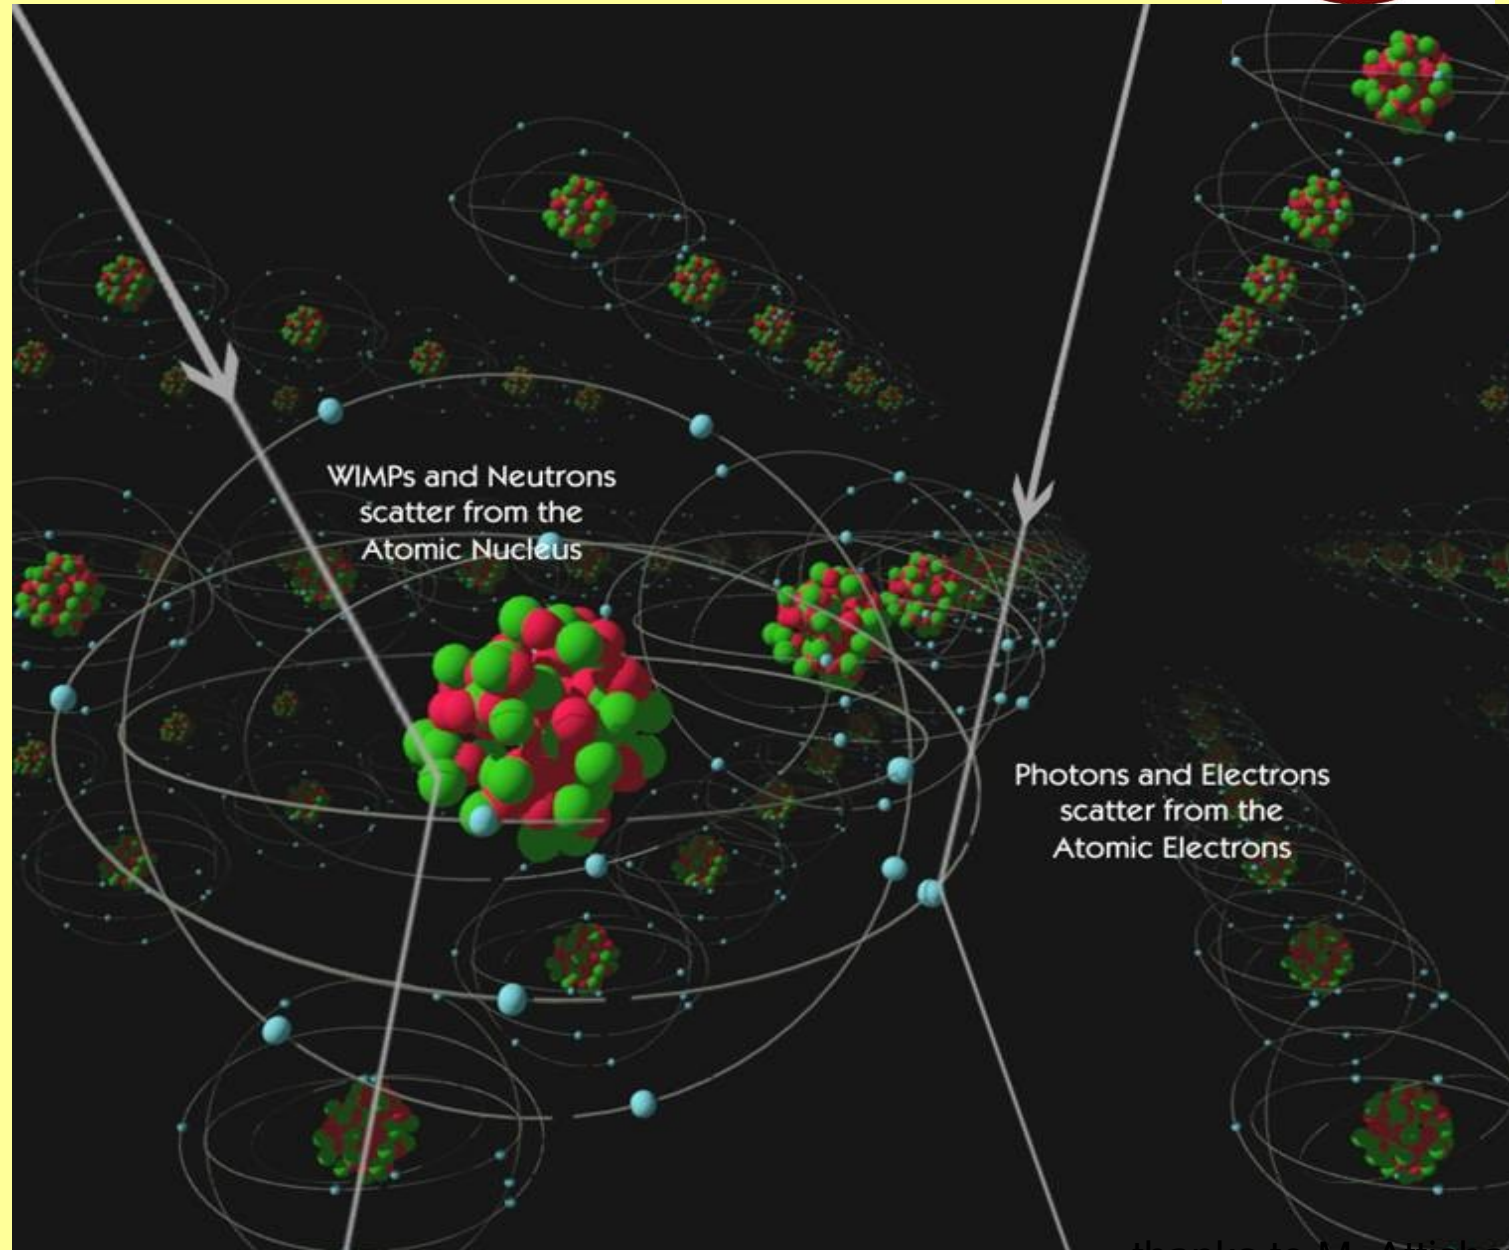

Electron recoil:

$$y = 1$$

Nuclear recoil:

$$y \approx 1/3$$

Yield is our main discrimination quantity.

thanks to M. Attisha

# Analysis chain

## **Blind WIMP Search data**

All interesting events are cut out from the data to ensure unbiased cut definitions

## **Select good WIMP Search runs**

## **Define fiducial volume**

Outer electrode signal is used to select events in the bulk region of the detectors

## **Define gamma and nuclear recoil band**

Energy dependence of yield discriminator and signal region definition.

## **Use timing information from phonon pulses to get rid of background**

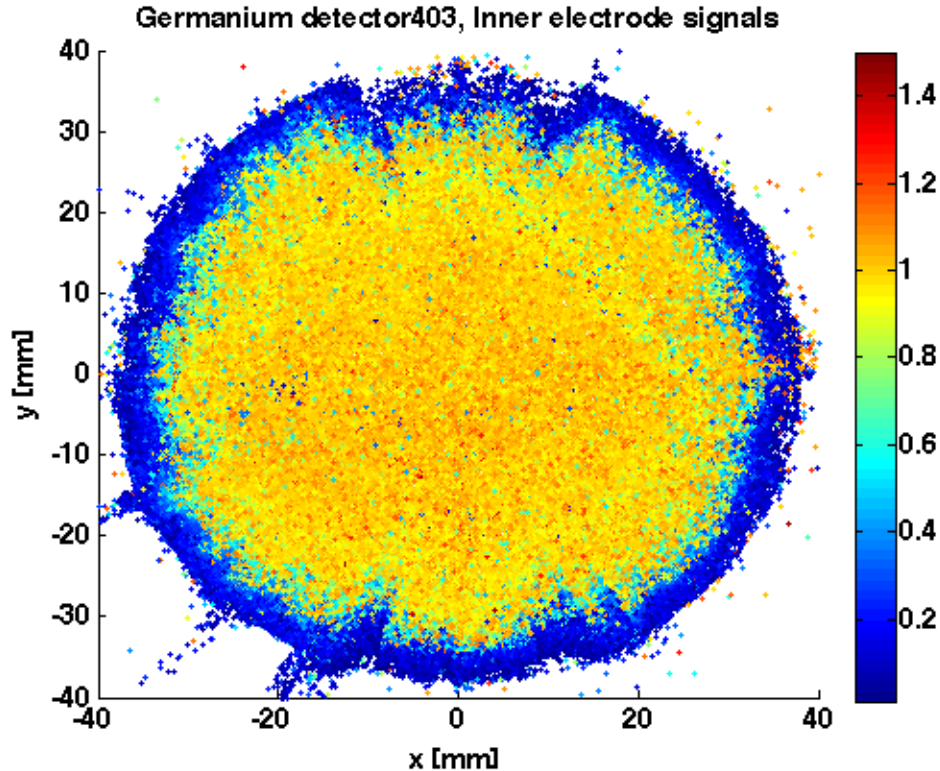

The timing properties of the phonon signal can be used to get rid of low yield events

## **Freeze cuts and calculate efficiencies**

Cuts are freezed and efficiencies of the cuts are calculated before unblinding.

## **Unblind WIMP Search data and see what is left after applying selection cuts**

# Inner-electrode cut

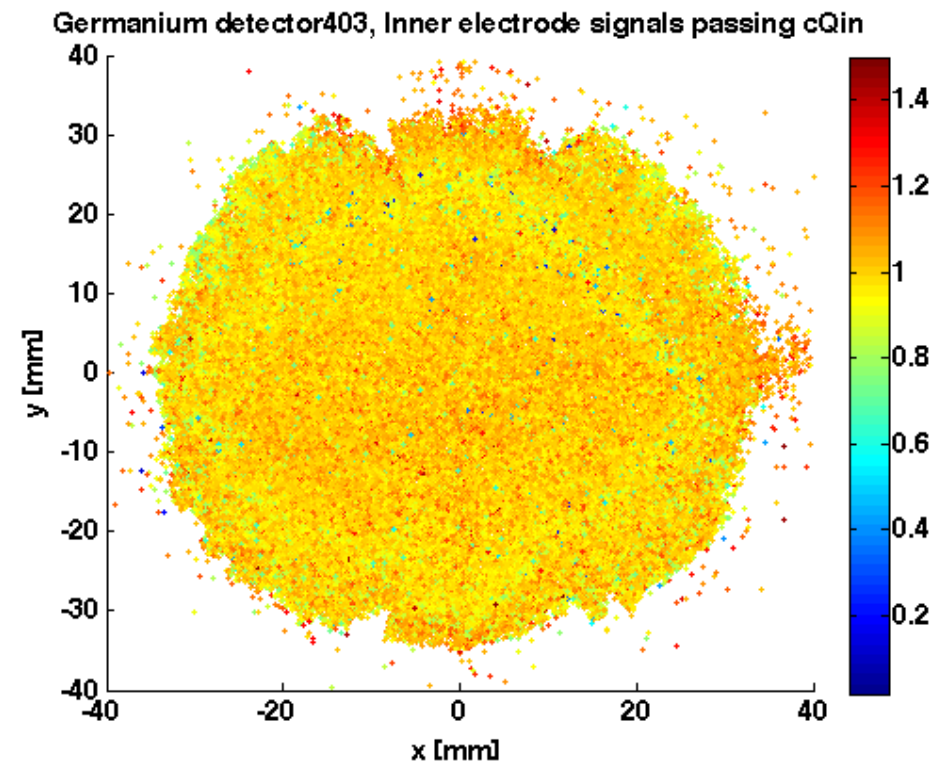

The outer electrode signals can be used to select events which are in the bulk region of our detectors.

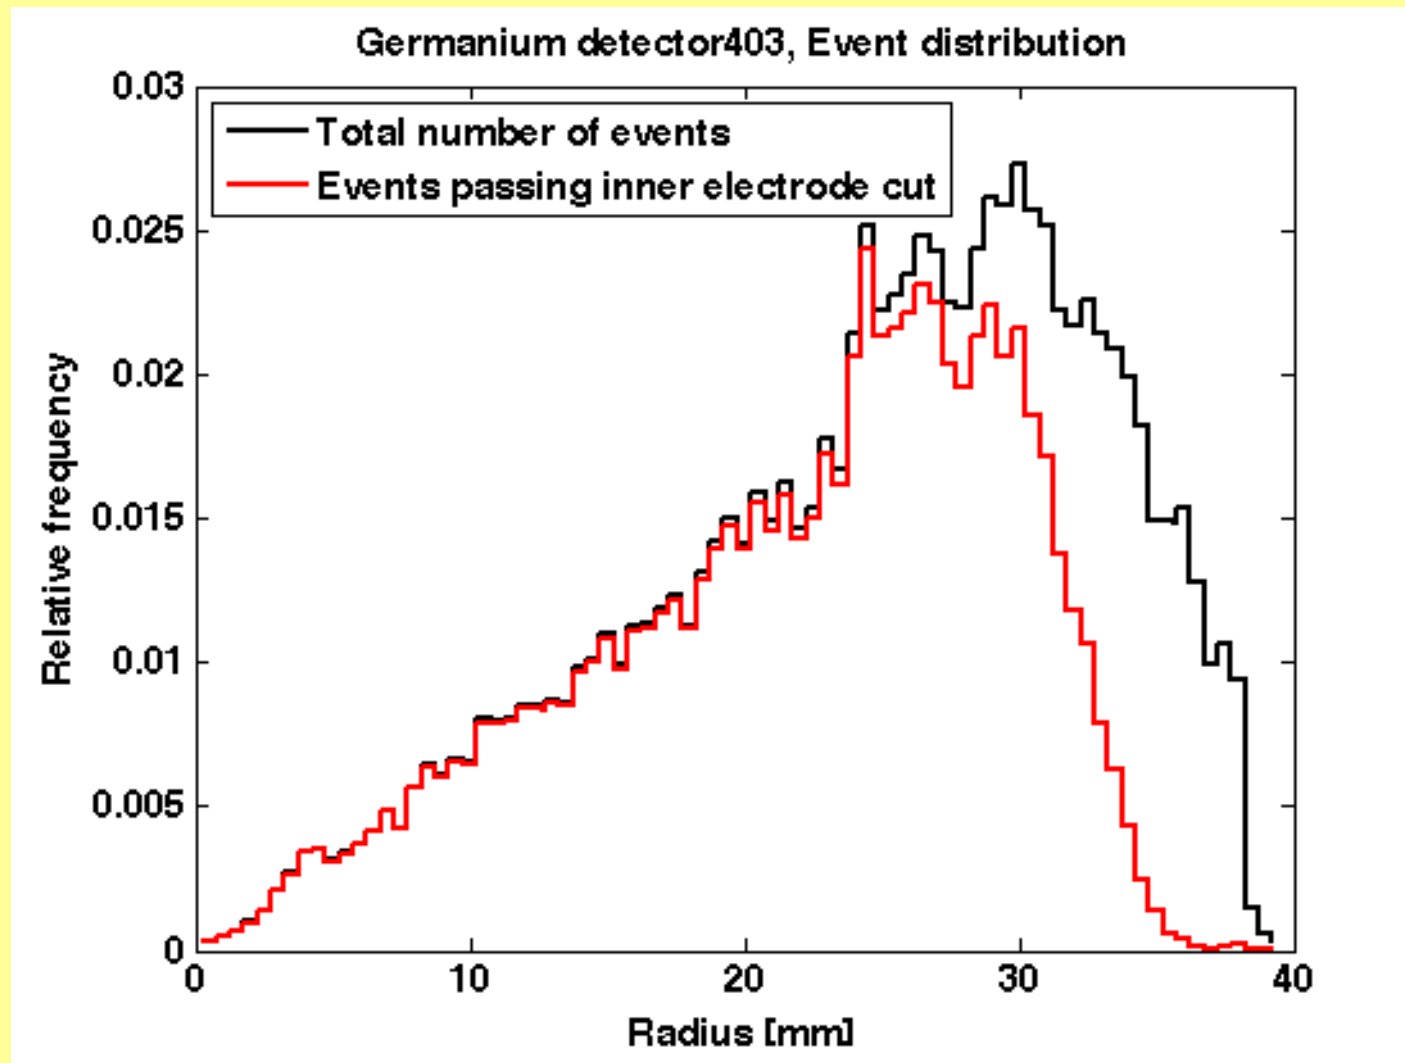

Incomplete charge collection for events at the crystal edges, could mimic nuclear recoils.

Complete charge collection for the majority of bulk events.

We will focus on bulk events with incomplete charge collection later.

# Radial distribution of $^{133}\text{Ba}$ calibration events

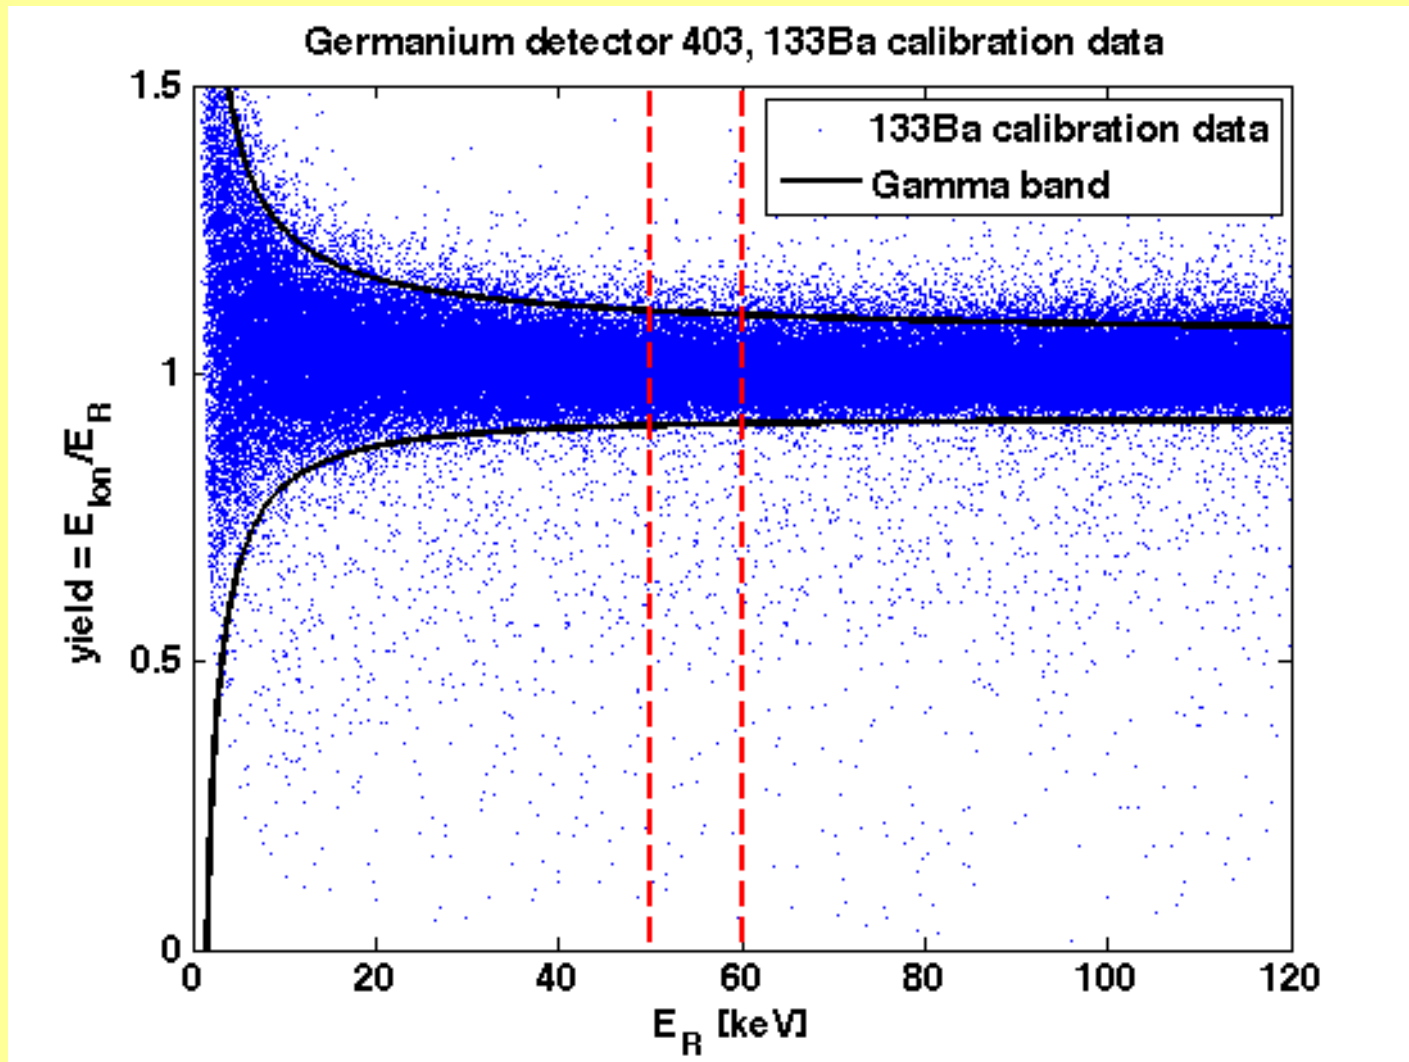

No sharp cutoff through inner electrode cut.

Fiducial volume is determined by the efficiency of the inner electrode cut applied to  $^{252}\text{Cf}$  calibrations.

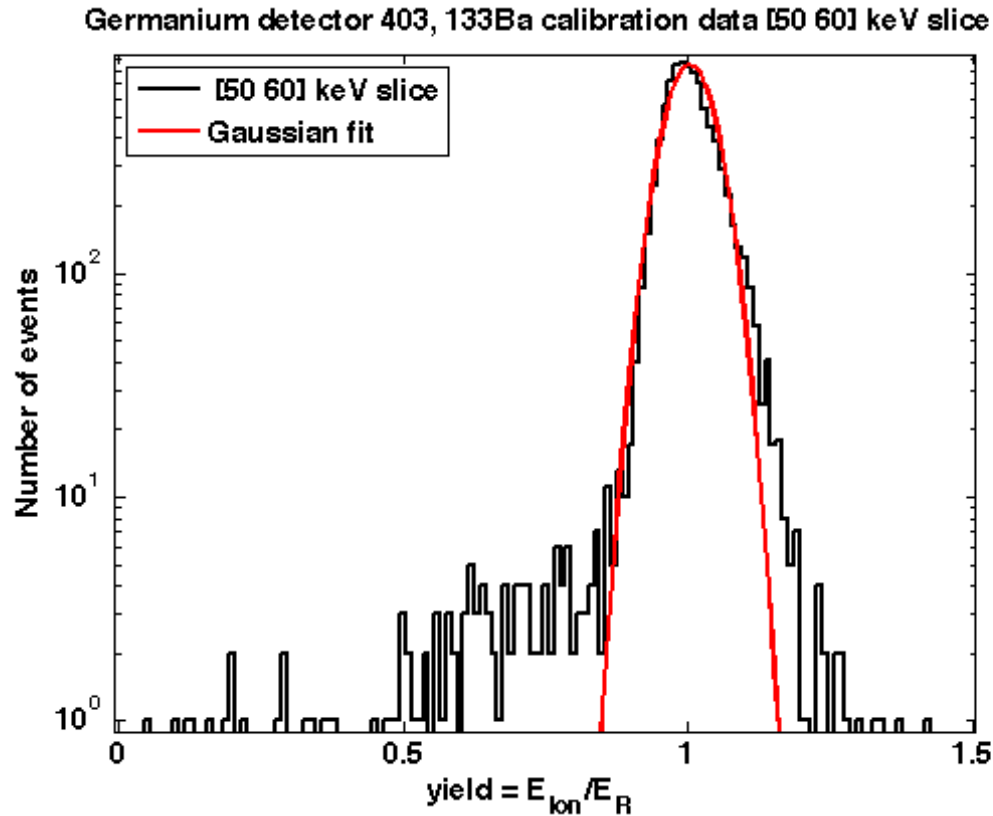

# Constructing the gamma-band

The gamma band defines the region of electron recoils and is constructed by  $^{133}\text{Ba}$  calibrations.

# Gaussianity and low-yield events

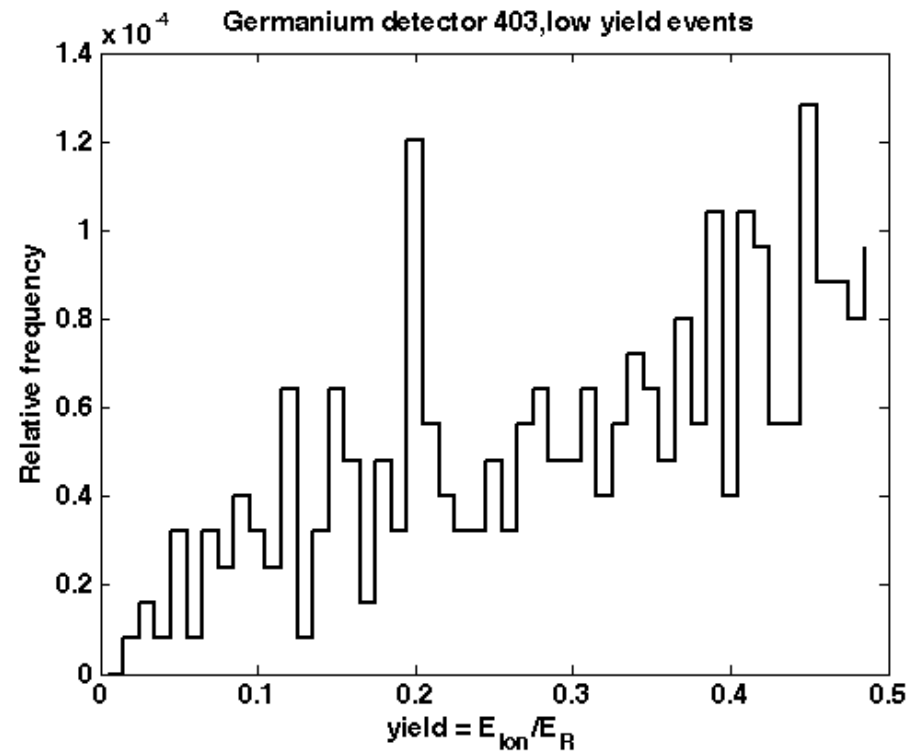

The mean and width of the gamma band is determined by fitting a gaussian to the data.

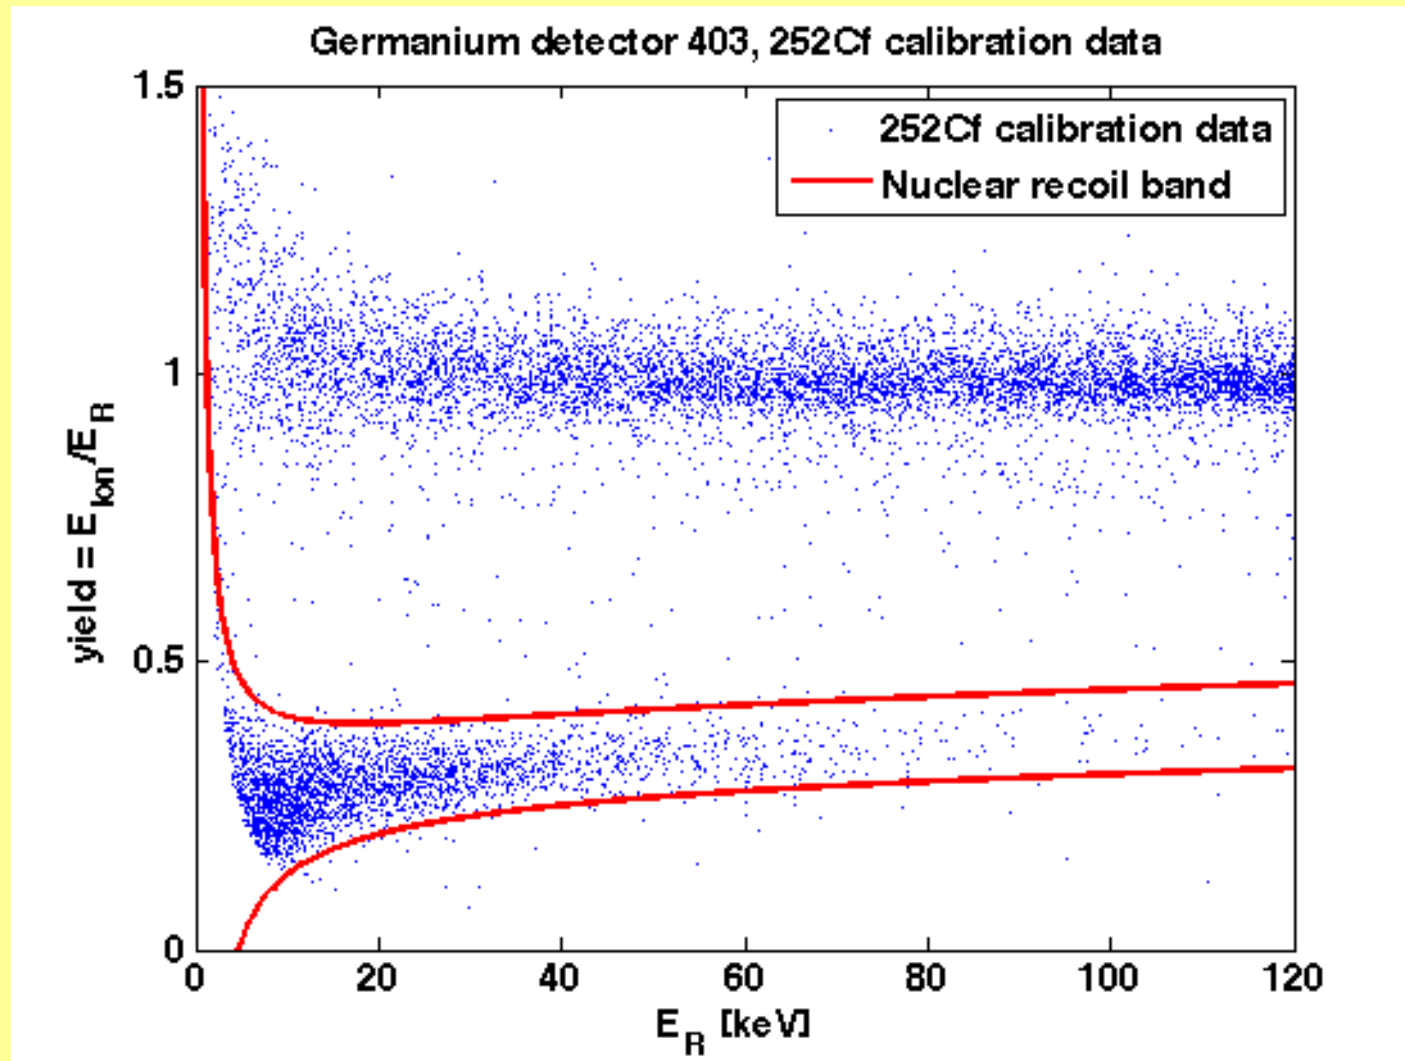

The non gaussian outliers are not considered in the definition of the band.

Non-gaussian outliers are rare but they are our main background.

We will deal with these low yield events later in the analysis.

# Defining the nuclear-recoil band

The nuclear recoil band is defined the same way as the gamma band, by using  $^{252}\text{Cf}$  calibrations

Since WIMPs are expected to give nuclear recoils, the  $2\sigma$  nuclear recoil band defines our signal region.

# First look at blinded low background WIMP-Search data

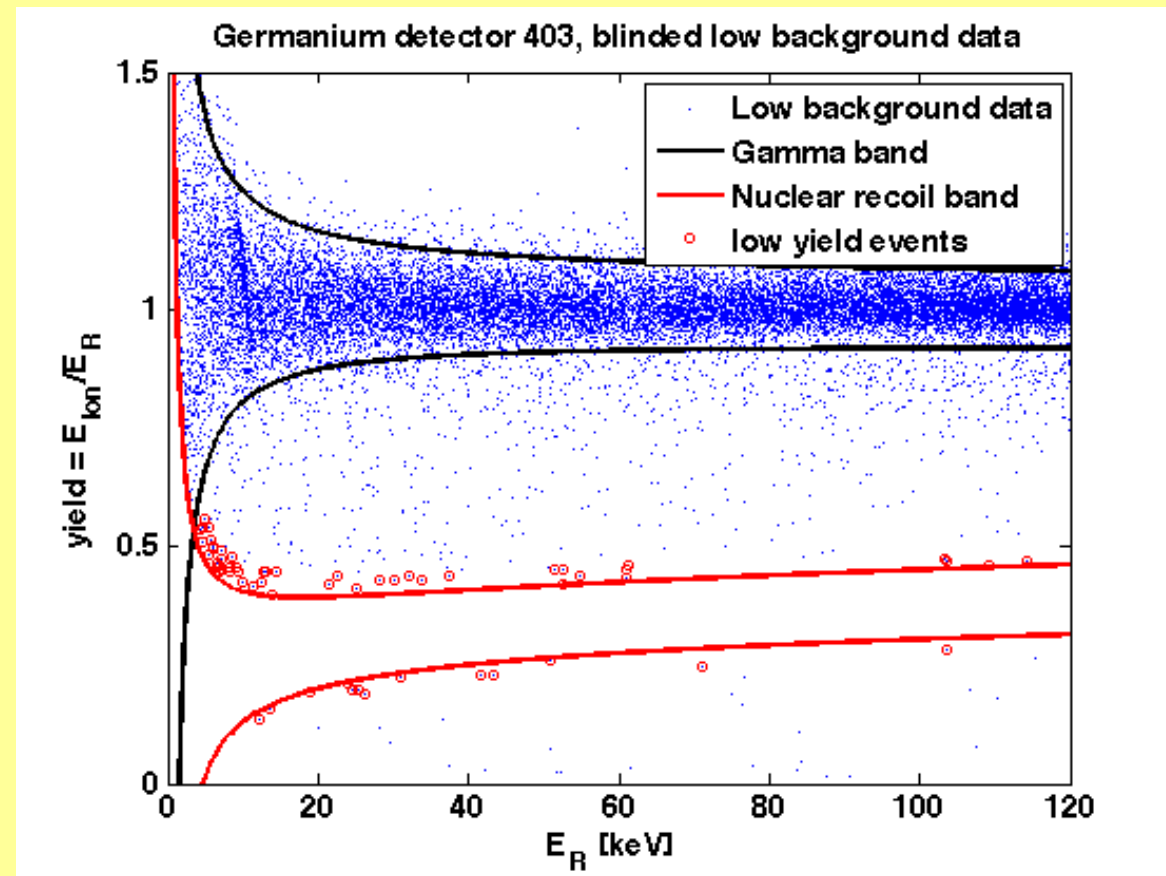

The analysis of the WIMP search data is performed „blind“ (there are no events in the Signal region during the analysis). This ensures a non biased definition of selection cuts.

Since surface events suffer from back – diffusion of the charge carriers, they do have an incomplete charge collection.

Incomplete charge collection lowers the yield discriminator of these events. They leak into the signal region, and mimic nuclear recoils.

Low yield events are our main and most dangerous background.

Discrimination of these events is achieved by using timing information of the phonon signals.

# Understanding the origin of our background

Natural radioactivity of our materials is causing our gamma background. MC simulations of known background sources matches the observed spectra very well.

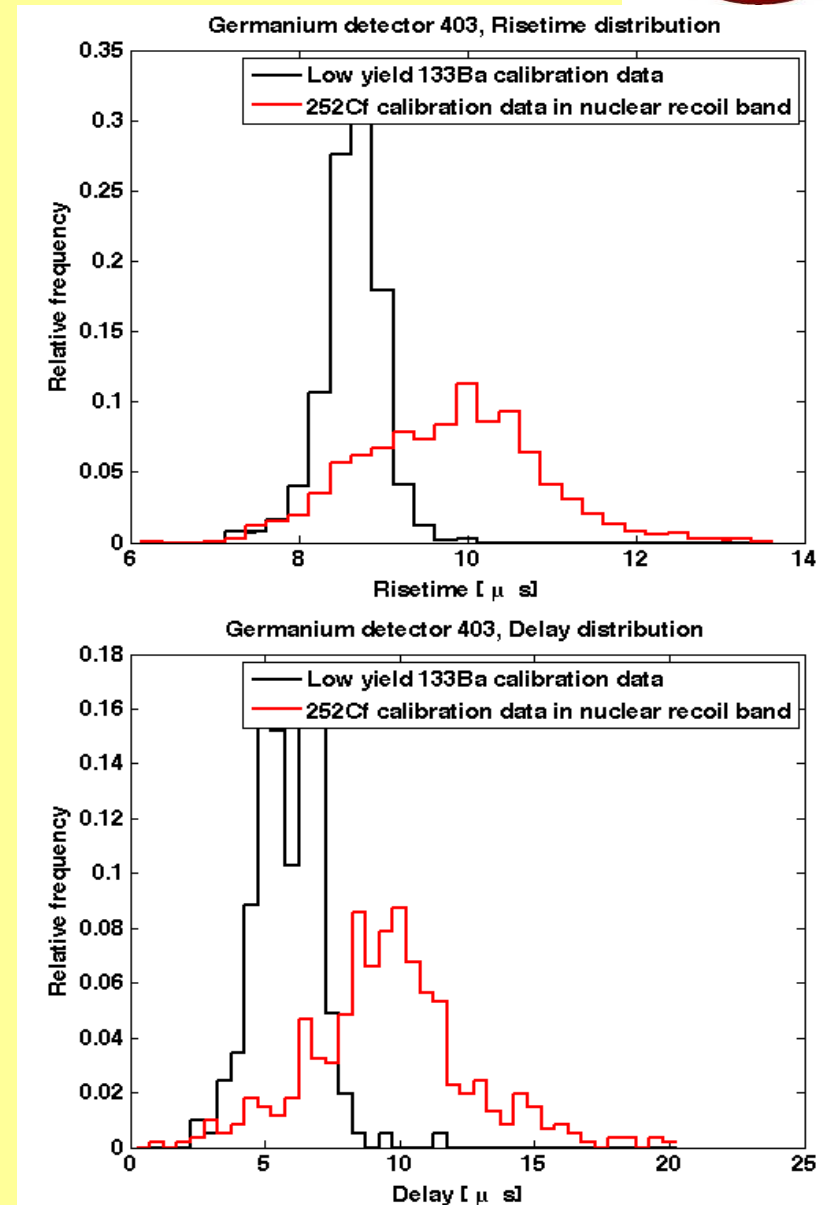

# A closer look at low yield events and differences between surface events and nuclear recoils

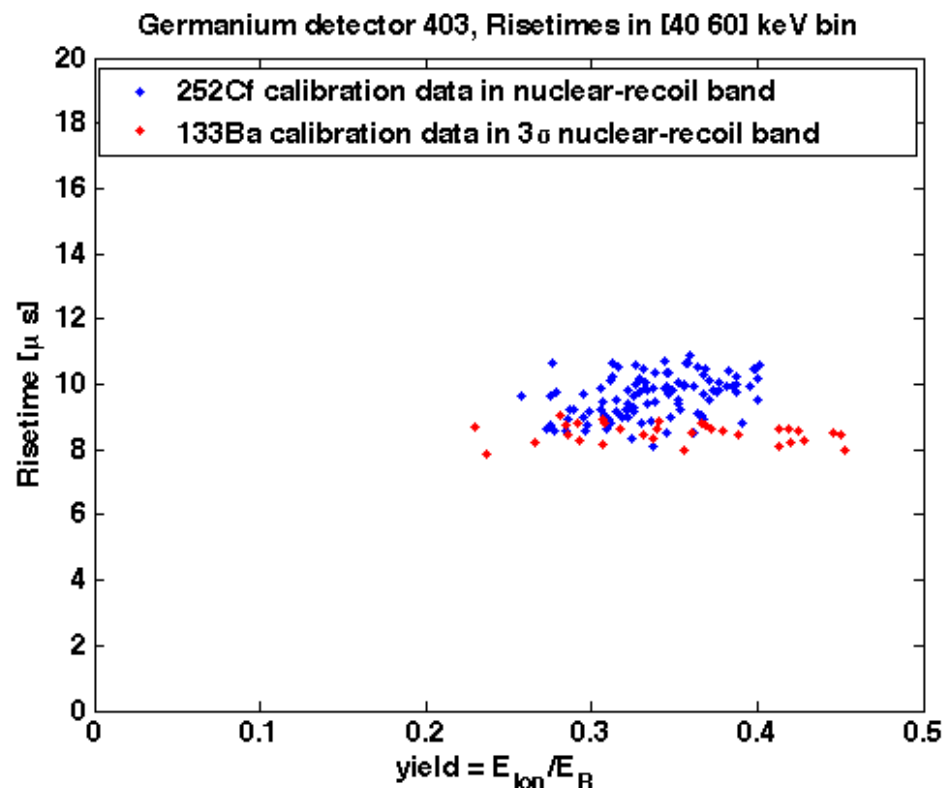

thanks to J. Filippini

Surface events are faster in timing than bulk nuclear recoils.

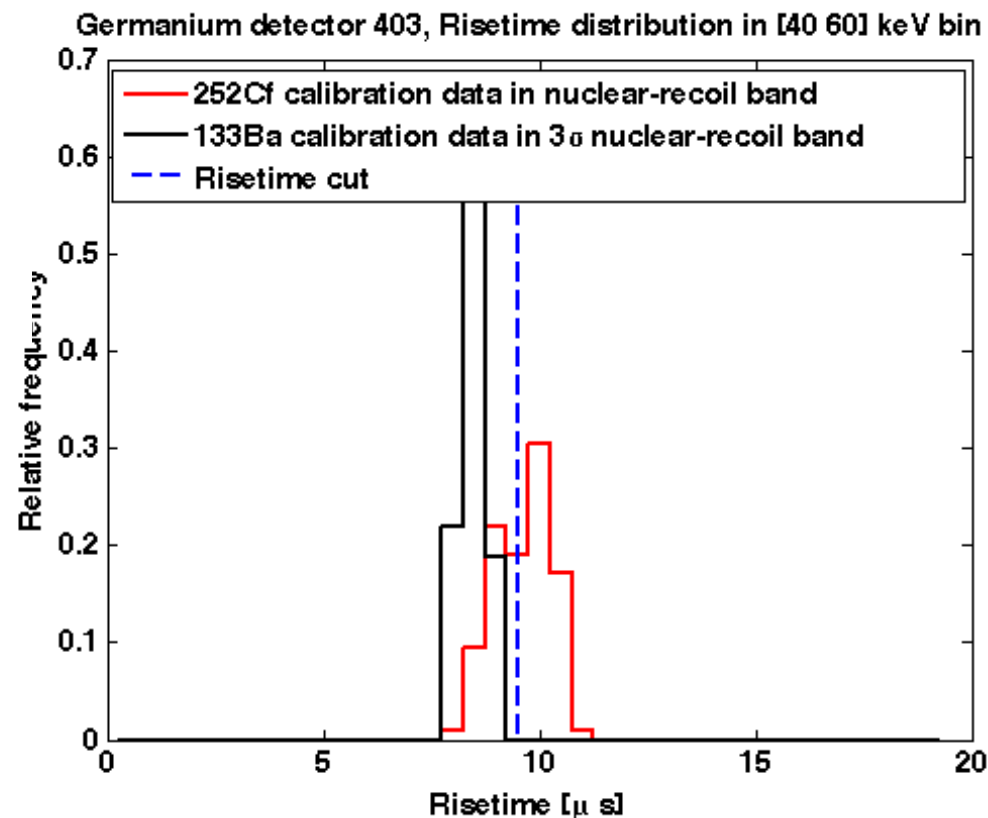

Timing is a powerful discriminator, used to get rid of low yield events, providing a **background free** signal region.

# Risetime of the phonon signal

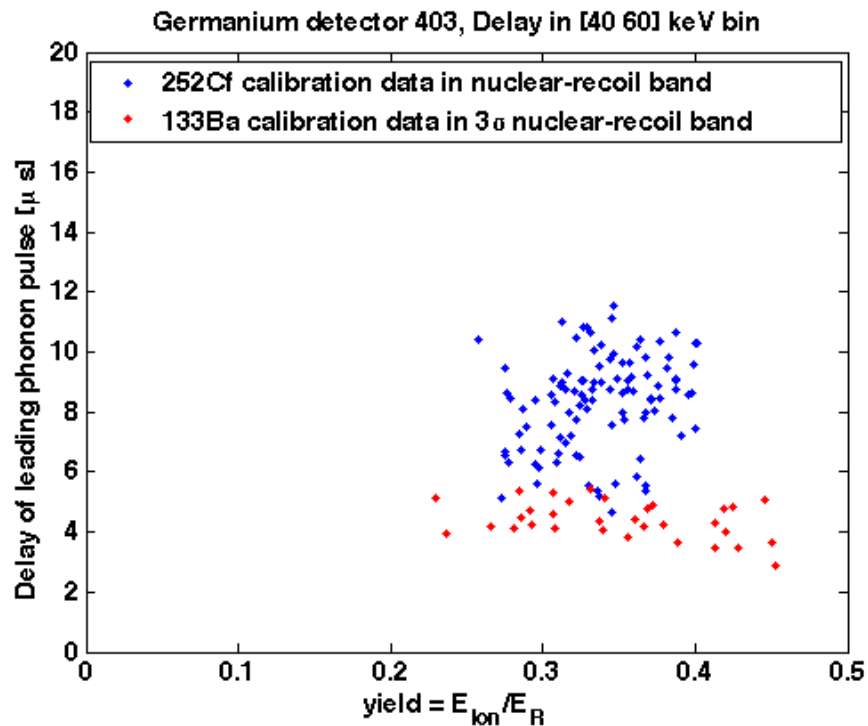

Even in the timing properties there are some gamma (beta) recoils which look like nuclear recoils.

Cuts on the timing properties like risetime or delay can be set, which select nuclear recoils.

# Delay of the phonon signal

Because of high energetic phonon downconversion, the delay of the phonon pulse has great discrimination power.

Cut can be set, such that all selected 133Ba events are excluded.

# Cut on phonon- timing parameters

Germanium detector 403, Delay vs. Risetime of electron and nuclear recoils

By selecting only  $^{133}\text{Ba}$  events which lie in the nuclear recoil band, the actual distribution of risetime and delay may be underestimated.

## Being more conservative

To gain more statistics and spread in the timing parameters distributions, we do not only select events which are close to the nuclear recoil band.

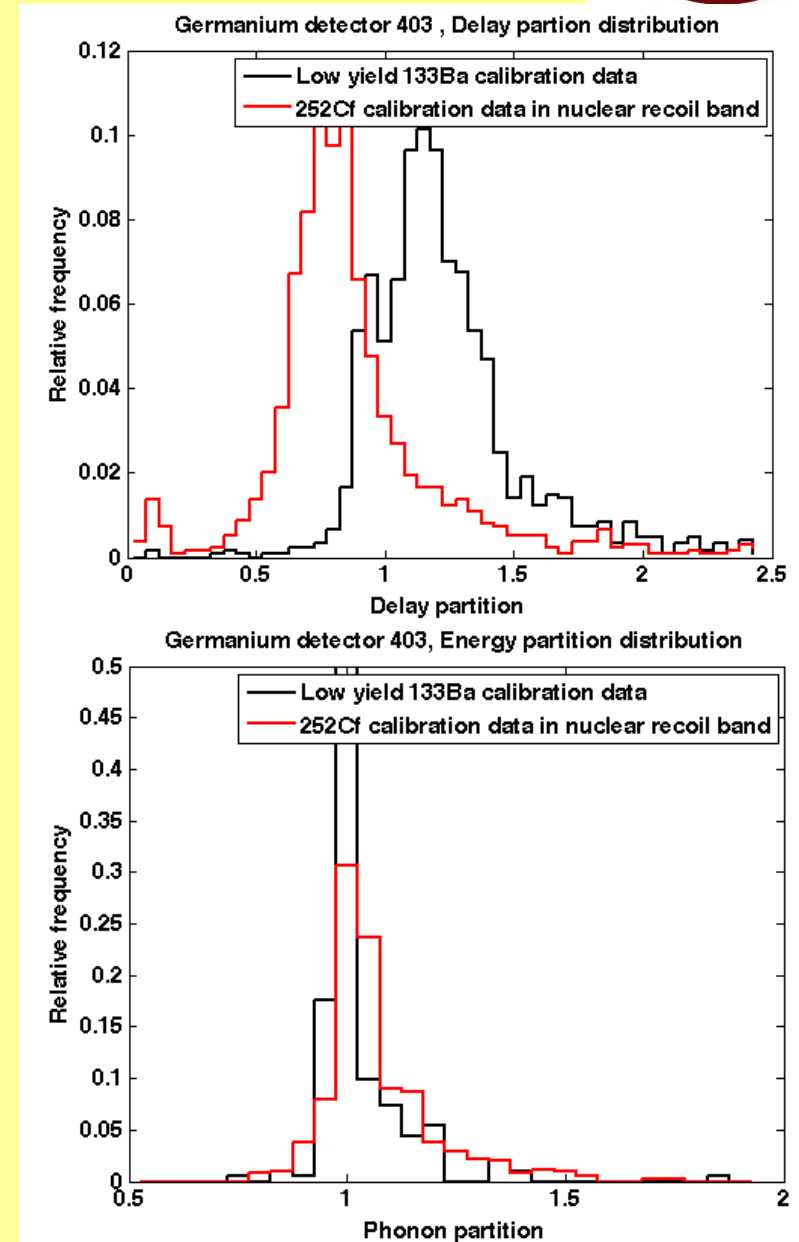

# Using more information to select nuclear recoils

thanks to J. Filippini

Parameters have not been used in past analysis (Run 118 + Run 119).

Parameters can be used in a extended timing analysis, to achieve better discrimination.

# Using Phonon timing to discriminate surface events

**Linear combination of risetime and delay:**  
A.Reisetter, PRL 96, 011302 (2006).

**Likelihood Analyses:** V.Mandic et al.  
NIM A 553 (2005)

**Cut-free** estimate of signal and background populations.

**$\chi^2$  – Analyses:** J.Filippini, R. Mahapatra,  
J. Sander

$$\chi^2_{\beta(n)} = (\vec{x} - \vec{\mu}_{\beta(n)})^T \cdot C_{\beta(n)}^{-1} \cdot (\vec{x} - \vec{\mu}_{\beta(n)})$$

3D (4D) space: risetime delay, delay  
partition (phonon partition).

**Neural Networks:** M.Attisha

Risetime, delay, phonon partition, wavelet  
components.

Train to distinguish nuclear recoils from  
surface events.

**Position Reconstruction:** R.W. Ogburn,  
G.Wang

Vary cut with position, tag surface events  
by face.

# $\chi^2$ analysis of timing parameters

In a  $\chi^2$  analysis the distance of each event from the neutron distribution (rn) and beta distribution (rb) is determined.

thanks to R. Mahapatra

Again cut can be set to exclude all betas while maximizing the neutron acceptance.

# Detection Efficiency

Our detection efficiency is determined by applying all cuts:

**DataQuality & Threshold & Band & Fiducial volume & Timing parameters**

to 252Cf calibration data

thanks to J. Yoo

Since our cuts are energy dependent, the detection efficiency is energy dependent.

Raw exposure and thereby sensitivity is reduced by this efficiency.

After all cuts have been freezed and efficiencies are calculated the WIMP search data is unblinded

# What is left after applying all cuts to the data?

The phonon timing parameters ensure a **background free** signal region.

# Results from Run 118 and Run 119

Run 118 WIMP-Search data after timing cuts, which reject most of electron recoils.

Phys. Rev. Lett. 93, 211301 (2004)

Run 119 WIMP-Search data after timing cuts, which reject most of electron recoils.

Phys. Rev. Lett. 96, 011302 (2005)

# Candidate event in Run 119 WIMP-Search data

Data set containing the candidate event was taken immediately after extended exposure to strong  $^{60}\text{Co}$  source.

After many interactions, charge build up in crystal:  
**deneutralization.**

Ionization collection is suppressed until the crystal is **reneutralized** by LED flashing.

# Status and plans for current setup at Soudan

## CDMS Detector Operation [5-Tower]

WIMP search starts : Sat Oct 21 16:25:08 2006  
Last update : Mon Jul 9 01:56:53 2007

Stable running for Run123 ended in March after 107.4 Live days.

After short maintenance period, cooldown for Run124. Stable running and data acquisition since May.

Ge (250g)  
Si (100g)

Ge raw exposure before physics cuts

**1st Run:**  
10/11/2003  
- 1/11/2004

52.6 kg-days

**2nd Run:**  
3/25/2004  
- 8/8/2004

93.1 kg-days

**3rd Run:**  
10/21/2006  
- 3/20/2007

430 kg-days

**4th Run:**  
April 2007  
- 2008

1200 kg-days

**Super CDMS**  
2008 -

*Thicker  
More detectors  
Longer exposure  
Higher bulk to surface ratio*

# What can we study if no candidate events are observed?

If no valid candidate events are detected (Run118+Run119) upper limits can be set on the WIMP nucleon scattering cross-section.

This mass dependent limits are independent of the nature of Dark Matter.

But they do depend on the assumed halo properties.

If  $\rho > 0.3 \rightarrow$  better limit.

If  $\rho < 0.3 \rightarrow$  worse limit.

Limit scales linear with local density.

# What can we study if candidate events are observed?

If candidate events are detected we want to determine the mass and crosssection of Dark Matter particles.

Simpelst approach would be a Likelihood estimation of confidencelevels.

Extendet Likelihood function is not  $\chi^2$  distributed for low statistics ( $n \leq 10$ ).

Confidencelevel determination by  $\ln L(\theta) = \ln L_{\max} - Q/2$  ( $Q=4.61$  for 90% CL and 2 dof) questionable.

Have to take „real“ data into account, possible improvement by Bayesian analysis.

Bayesian analysis needs prior, a certain parameter set for the true parameters has to be chosen which is a priori unknown.

# Feldmann - Cousins Likelihoodratios

Use Likelihoodratio to determine propability of a parameter point.

$$\chi(\theta_{point}) = \frac{L(n|\theta_{point})}{L(n|\theta_{best})}$$

disfavoured  $0 \leq \chi \leq 1$  favoured

G.J. Feldman, R.D. Cousins, Phys Rev. D 57 (1998), 3873-3889

Likelihoodratio accurate for low statistics ( $n \leq 10$ ).

For each parameter point run a lot of MC experiments and define  $\chi_c$  such that  $\alpha$  (CL) of these experiments have  $\chi \geq \chi_c$ .

For the „real“ data calculate  $\chi_{test}$  for each parameterpoint. Find confidencelevels by Likelihoodratiotest. ( $\chi_{test} \geq \chi_c$ ).

No need of prior, confidencelevels determined by Likelihood ratio test with „real“ data.

Needs a lot of computation time.

# Conclusions

The direct search for the nature of Dark Matter is frontier physics with an excellent interlink between high energy physics and astroparticle physics.

The CDMS experiment uses high end technology in the search for Dark Matter.

The CDMS experiment has an event by event discrimination between background and expected signal.

Analysis of the Run 123 data is in progress.

New analysis parameters and discriminants promise a **background-free** operation for current runs → **maximal discovery potential**.

# **Backup Slides**

# SuperCDMS at Soudan

New 1 inch thick ZIP detectors with an improved phonon readout.

ZIP used in the  
CDMS II setup.

x 2.54 mass.

ZIPs used in  
the first phase  
of SuperCDMS.

Improvement in phonon readout by new  
geometry of TESs, which maximizes the active  
Al coverage.

First results show an improved yield  
discriminator for 1 inch detectors.

Installation of the first two SuperTowers at  
Soudan at the end of 2008.

# SuperCDMS at SNO-LAB

SuperCDMS will be split in four phases, with an increased mass at each phase reaching for a ton scale experiment.

## Phase A :

Operation of 7 SuperTowers with a total mass of 25kg at SNO-LAB.

Retaining zero background for SuperCDMS:

Background rejection	×4
Analysis discrimination	×2
Background reduction	×5
<b>Total Improvement</b>	<b>= ×40</b>
Production rate per kg	×5

Table 2: Targeted improvement factors over CDMS II advanced analysis levels (see Section 3.2) to achieve SuperCDMS 25 kg sensitivities with zero background from internal sources. The cosmogenic fast-neutron background is eliminated by the SNO-LAB overburden of 6000 mwe.

Muon induced neutron flux negligible at SNO - LAB.
